

# On source identification with footprints

Rostislav Kouznetsov  
Marje Prank

## Outline:

- ▶ Footprints and source identification
- ▶ (4+1)D sensitivity patterns
- ▶ Example1: Soot in snow samples
- ▶ Example2: GHG monitoring in Tiksi

# Trajectories

INDOEX, 99 H4 Data from File: feb04h06-5.dat

Trajectory arriving at the ship on JDAY 35.25

- ▶ Trajectory – back track of air parcel from receptor
- ▶ Very simple, intuitive and misleading
- ▶ Ignores diffusion, deposition, transformation
- ▶ Single or few trajectories provide little information
- ▶ No way to locate sources
- ▶ Density of trajectories is needed

# Backwards modelling

- ▶ Reverse time
- ▶ Starts from the receptor
- ▶ It is NOT the way to inverse dispersion

# Backwards modelling

- ▶ Reverse time
- ▶ Starts from the receptor
- ▶ It is NOT the way to inverse dispersion

Can't meance the meat  
back. . .

# Footprint

Forward:

$X\%$

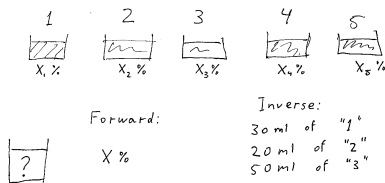

Inverse:

30 ml of "1"  
20 ml of "2"  
50 ml of "3"  
-----

Question: How strong each of initial liquids was?

# Sensitivity

- ▶ Sensitivity does not tell where the source is
- ▶ It tells how sensitive particular sample is to emissions at different locations and times
- ▶ Footprint for each sample (number) is 4D field
- ▶ Can be used for source apportionment if some additional info is available

Example: Clean sample + assumption of persistent changing sources allows to exclude the area

- ▶ Huge amount of data
- ▶ Constant sources: Can be integrated over footprint time
- ▶ Constant source height: Only expected source height can be taken
- ▶ Can be weighted/filtered/censored according to observational data

End up with observable amount of maps. . .

# Example 1: Soot in snow

## Input:

- ▶ Mass concentration of soot in  $\sim 50$  samples of surface snow collected weekly

## Problems:

- ▶ What are the concentrations responsible for snow contamination?
- ▶ Effect of local sources?
- ▶ Effect of dry deposition?
- ▶ What PM soot is?
- ▶ Snow falls?

# Example 1: Soot in snow

## Input:

- ▶ Mass concentration of soot in ~50 samples of surface snow collected weekly

## Problems:

- ▶ What are the concentrations responsible for snow contamination?
- ▶ Effect of local sources?
- ▶ Effect of dry deposition?
- ▶ What PM soot is?
- ▶ Snow falls?

## Solutions:

- ▶ Constant scavenging below cloud, none within cloud
- ▶ Friday samples
- ▶ Only after-snowfall samples
- ▶ Run passive gas, fine and coarse particles
- ▶ Only when meteorological observations reported snow

Compare average “clean” and “dirty” footprints.

# Snowfalls in met.model

2009-12-03 -- 2009-12-05

2010-03-25 -- 2010-03-27

2010-11-18 -- 2010-11-20

2011-01-27 -- 2011-01-29

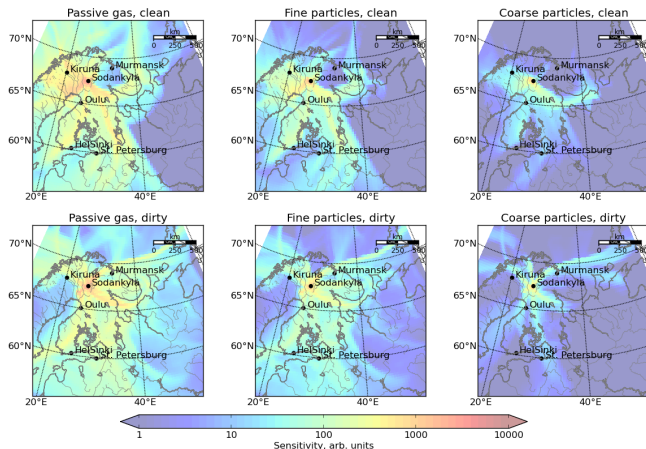

# Clean and dirty footprints

# Exercise results

- ▶ Stronger washout – more compact footprint
- ▶ Kola peninsula contributes to “dirty” samples, but does not contribute to “clean”

## Example 2: CH<sub>4</sub> from the sea bed?

Input:

- ▶ Hourly time series of CH<sub>4</sub> and CO<sub>2</sub> concentrations at Tiksi

Problems:

- ▶ No constant background
- ▶ What is “clean” and what is “dirty”?

## Example 2: CH<sub>4</sub> from the sea bed?

Input:

- ▶ Hourly time series of CH<sub>4</sub> and CO<sub>2</sub> concentrations at Tiksi

Problems:

- ▶ No constant background
- ▶ What is “clean” and what is “dirty”?

Solution:

- ▶ Band-pass filter time series
- ▶ Weight footprints according to signal components

# Weighted footprints

# Weighted footprints

CH4-exc x 10, 6h -- 12h

CO2-exc

unity

# Weighted footprints

CH4-exc x 10, 12h -- 24h

CO2-exc

unity

# Weighted footprints

CH4-exc x 10, 24h -- 48h

CO2-exc

unity

# Weighted footprints

CH4-exc x 10, 48h -- 96h

CO2-exc

unity

# Weighted footprints

# Exercise results

- ▶ CH<sub>4</sub> has more compact footprint
- ▶ Sources of CO<sub>2</sub> can be clearly traced (shipping, industries)
- ▶ Band-pass decomposition works when background is unknown

- ▶ Footprints are better than trajectories
- ▶ It is not the way to do “inverse” dispersion
- ▶ Require data reduction and interpretation
- ▶ Powerful tool for source identification (works for isolated sources)
